Dark Matter in Galaxies

1 JYOTI P. BISWAS, State Univ of NY- Stony Brook — In 1933, while examining the Coma galaxy cluster, Fritz Zwicky was the first to infer the existence of unseen matter, which he referred to as dark matter. He calculated the gravitational mass of the galaxies within the cluster and obtained a value at least 400 times greater than expected from their luminosity, which means that most of the matter must be dark. In the late 1960s and early 1970s, Vera Rubin, measured the Rotation curve of edge-on spiral galaxies and she also fund that, there must be unseen mass that is holding the galaxies. Scientist started to explain the fact by Modified Newtonian Dynamics. Soon it was found that Modified Newtonian Dynamics is not solely responsible for the explanation of unseen mass. From then lots of explanation was given to explain the Dark Matter. But recent observation firmly concluded the existence of Dark. Although, it has been confirmed the existence of Dark Matter in Galaxies, yet it is not directly detected by experiment. Scientists all over the world are trying to detect the Dark Matter Particle. We hope that, within few years scientists will be able to create Dark Matter in LHC or directly detect the particle to explain the History of the Universe.
